Introduction

- We consider a finite difference approximation with summation-by-parts operators and weakly imposed boundary conditions.
- The boundary conditions are imposed with the simultaneous approximation terms (SAT).
- Given a well-posed problem, the numerical approximation is made stable with appropriate choices of penalty terms.

Introduction

- The method has been extended to cover a close-boundary domain, where the solution is assumed to be known.

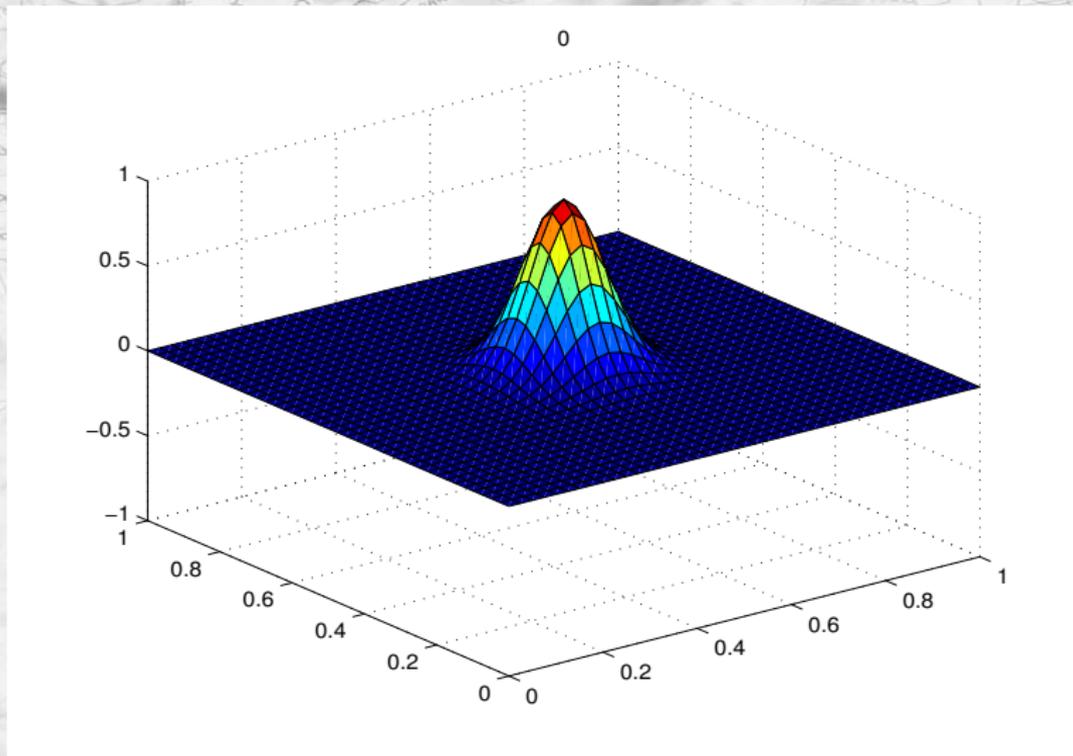

Introduction

- The multiple penalty technique adds flexibility to the scheme.
- Stability can easily be guaranteed.
- Straight-forward to implement and generalize to multiple dimensions.
- Puts new demands on the knowledge of the problem: the solution needs to be known in the extended domain.
